Abstract. The next generation of tightly interconnected vehicles offers a variety of new technologies as well as business opportunities. Vehicles form so-called vehicular ad hoc networks (VANETs). Sophisticated systems of interconnected cars in the context of VANETs assume a full coverage of 5G networks to unfold their full potential. However, nowadays network infrastructure is neither 5G-ready nor does it provide reliable and full coverage of all areas that might be relevant for VANET-based networks. Hence, the conventional mode of operations of all nodes being connected to one blockchain at all times is not feasible. In addition, traditional blockchains also require every node to process each transaction and smart contract commands which are highly inefficient. Therefore, we present a solution based on so-called mobile ad hoc blockchains that enable groups of nodes involved in any kind of collaboration to effectively form temporary networks and coordinate themselves. Another critical requirement of VANETs and interconnected vehicles is security. The safety of network participants does not only depend on the vehicle's hardware, but also on the correctness of the software that controls the interaction and transaction within the network. Formal verification is a common way to address the issue proving the correctness of software. The self-amending blockchain Tezos supports Turing-complete smart contracts and also offers built-in formal verification of their programming languages, thereby fostering the security of our solution. This whitepaper fills the gap by introducing Vehicular Ad Hoc Tezos Blockchains based on mobile ad hoc blockchains that allow groups of nodes to be temporarily disconnected from the overall network but still being able to enact and transact on a local network level for the duration of their interaction. We present the advantages of the system, outline the requirements and goals, as well as the architecture of the system.

Keywords: VANET, Formal Verification, Tezos, Mobile Ad Hoc Blockchains, Blockchain, Smart Contracts, Interoperability, Vehicle Networks, V2X

1 Introduction

Despite steadily growing public transport networks and systems, especially in most first world countries, cars are still the default standard for urban trans-

portation. In the US, “about 86 percent of all workers commuted to work by private vehicle, either driving alone or carpooling” [20], even though in recent years the numbers remained relatively stable after decades of consistent increase. Similar applies to other industrial countries [21][12] though the overall percentage of vehicle commuters in Europe is lower than in the US [8]. While it was normal for the last few decades to own a vehicle and commute on a day-by-day basis, the future will be radically different due to the progressing evolution of self-driving cars and autonomous vehicles. The car-sharing economy that developed in recent years in combination with autonomous cars results in a so called *passenger economy* [14]. Users no longer own cars, instead just hop on an autonomous car, pick a destination and get delivered without any human interaction. An Intel report estimates the size of this economy to be around US\$ seven trillion in 2050 [14].

A key technology for the next generation of tightly interconnected vehicles are so-called vehicular ad-hoc networks (VANETs) [?]. Vehicles form VANETs enable vehicle-to-vehicle (V2V), vehicle-to-infrastructure (V2I), vehicle-to-human (V2H), or in general vehicle-to-everything (V2X) communication and interaction. In our previous research paper [?][?][?], we presented a blockchain-based system that enables a manufacturer agnostic platform solution that allows VANET participants to enact and transact any kind of services and goods. Sophisticated networks of interconnected cars require full coverage of 5G networks to unfold their full potential [?]. However, nowadays network infrastructure is neither 5G-ready nor does it provide reliable and full coverage of all areas that might be relevant for VANET-based networks. Hence, the conventional mode of operations of all nodes being connected to one blockchain at all times is not feasible [?]. In addition, traditional blockchains such as Bitcoin [22] and Ethereum [27] also require every node to process each transaction and smart contract commands which are highly inefficient. Therefore, we present a solution based on so-called mobile ad hoc blockchains that enable groups of nodes involved in any kind of collaboration to effectively form temporary networks and coordinate themselves. They only connect to nodes they need to be connected to, depending on the context, for the duration of their interaction.

Another critical requirement of VANETs and interconnected vehicles is security. The safety of network participants does not only depend on the vehicle’s hardware, but also on the correctness of the software that controls the interaction and transaction within the network. Formal verification is a common way to address the issue proving the correctness of software with respect to a certain formal specification or property using formal methods of mathematics [?][?]. The self-amending blockchain platform Tezos [13] does not only support Turing complete smart contracts, it also offers built-in formal verification of their smart contract programming languages, thereby fostering the security of our solution.

This work fills the gap by introducing Tezos-based platform solution, thereby answering the question of how to enable vehicular ad hoc blockchains that allow groups of nodes to be temporarily disconnected from the overall network but still being able to enact and transact on a local network level for the duration of

their interaction? In order to answer this question with a separation of concerns, we pose the following sub-questions: What is the corresponding architecture of the Vehicular Ad Hoc Tezos Blockchain? What are the detailed network and communication processes? What kind of use cases and application scenarios exist?

The remainder of this paper is structured as follows: Section 2 introduces supplementary literature and related work. Section 3 outlines the system architecture our solution. Afterwards, Section 4 expands on the network communication processes, followed by Section 5 that introduces example use cases and application scenarios. Finally, Section 6 concludes this work and provides an outlook on future work.

2 Technical Background and Supplementary Literature

The following section provides background information and describes related works regarding previous ideas and concepts that focus on a blockchain-based VANET platforms. First, Section 2.1 introduces the general concepts of blockchain technology, terms and frameworks. Afterwards, Section 2.2 and Section 2.3 focus on the fundamentals of vehicular ad-hoc networks as well as formal verification. Finally, Section 2.4 introduces related work.

2.1 Blockchain Technology

As the name suggests, a blockchain consists of a chronologically ordered chain of blocks. Every block consists of a certain number of validated transactions and each of those block links to its predecessor by a hash reference. As a result, changing the content of one block also changes all succeeding blocks and hence breaks the chain. All blocks are stored on and verified by all participating nodes. While the initial Bitcoin blockchain only supported a very limited set of scripting instructions, the next generation of blockchain platforms, e.g., Ethereum [27], Qtum [9], or Tezos [13], provide Turing-complete programming languages on the protocol-layer level in order to enable smart contract capabilities. Smart contracts are “orchestration- and choreography protocols that facilitate, verify and enact with computing means a negotiated agreement between consenting parties” [9]. Hence, the entities participating in the enactment of a smart contract establish binding agreements and deploy applications using such smart contracts in order to provide blockchain-based applications. Those application are as versatile as smart contracts itself and enable services including the finance sector [23][25], academic and business authentication and identity solutions [4][7][16][19][26], reputation systems [5] as well as platforms for Internet-of-Things (IoT) applications [6][24].

The blockchain concept is particularly interesting for the V2X economy for three reasons. First, it removes the need for trusted third parties and instead enables trust-less transaction enactment. Second, transactions that were agreed up on cannot be changed later on since the underlying blockchain is tamperproof.

Third, no human interaction is required for any kind of transaction between vehicles or machines in general.

2.2 Vehicular Ad-Hoc Networks - VANETs

Communication between vehicles, road infrastructure and Internet-based services is a key enabler for the upcoming generation of vehicles. So called vehicular ad-hoc networks provide an abstract concept that models the different components that are required for V2V, V2I, or V2X communication. Figure 1 illustrates the main components of VANETs: Vehicles, on-board-units (OBUs), application-units (AUs) and road-side-units (RSUs).

RSUs are placed along the road side or in dedicated locations such as at cross-roads. Typically, RSUs provide short range communication based on IEEE 802.11p radio technology but can also be equipped with other network devices in order to provide communication within the infrastructural network [1]. OBUs are mounted onto a vehicle and used for data exchange. To do so, short range wireless- or radio communication is used to exchange these information [3]. Closely linked to the OBU is the AU, they might even reside in the same physical unit or as a mobile unit that is regularly removed from the vehicle (e.g smartphones). The AU provides an execution environment for applications that utilize the OBU's communication capabilities [1][3].

Communication in VANETs occurs either inside a vehicle between AUs and

Fig. 1. General VANET architecture (Based on [3] and [17])

OBU, wirelessly between different vehicles (V2V), vehicles and infrastructure

(V2I) or vehicles and the infrastructure via broadband (V2B) [10]. For authentication purposes, each network participant is equipped with a unique public/private key pair that resides in a tamper-proof-device (TPD). In blockchain terms, the TPD is similar to an external hardware wallet.

2.3 Formal Verification

ADD some FV stuff + sources here – TAKE STUFF FROM THE AUTHCOIN MASTER THESIS [15] (Section 1.1.2)

basic introduction with motivation, advantages and disadvantages A380 example?

connect formal verification and blockchain tezos [13] cardano [?] others?
